

1                           ABSTRACT

2         The instant invention involves the use of a  
3         combination of preparatory steps in conjunction with mass  
4         spectroscopy and time-of-flight detection procedures to  
5         maximize the diversity of biopolymers which are verifiable  
6         within a particular sample. The cohort of biopolymers  
7         verified within such a sample is then viewed with  
8         reference to their ability to evidence at least one  
9         particular disease state; thereby enabling a diagnostician  
10        to gain the ability to characterize either the presence or  
11        absence of said at least one disease state relative to  
12        recognition of the presence and/or the absence of said  
13        biopolymer, predict disease risk assessment, and develop  
14        therapeutic avenues against said disease.
